

Diagrams Module in Python

Description

- Diagrams allows you to create diagrams with code using Python. It is a great alternative to build system level diagrams in lieu of enterprise visualization tools.

Setup

1. `diagrams` uses `graphviz` as a dependency in order to work so you have to install `graphviz` on your operating system.

Windows

- Windows 11 - Use `winget`

1. Go to [Winget](#)
2. Search for `Graphviz` .
3. Click on `Copy` command
4. Paste the command in a Terminal.

- Windows 10 - Use `chocolatey`

1. Within an Administrator Command Prompt, type in the following command:

```
choco install graphviz
```

- Mac - Use Homebrew

1. Within a Terminal, use the following command:

```
brew install graphviz
```

2. Install the following packages using `pip`

```
graphviz  
diagrams
```

- Within a Terminal, type in the following command:

```
pip install -r requirements.txt
```

Basic Usage

- Diagrams essentially operates on a graph structure which means that you have nodes, edges, and clusters.
- A diagram has its own context which means you have to use the word `with` to manage whatever happens inside the diagram.
- Same is true for clusters that are inside the diagram.
- Use the `>>` between nodes to create relationships between the nodes.

```
from diagrams import Diagram, Node, Edge
```

```
with Diagram():  
    # Manage the context  
    node_one = Node(label='node_one')  
    node_two = Node(label='node_two')  
  
    node_one >> node_two
```

- If you want specialized logos for aspects such as the cloud or open source software, you can get all the logos from the official documentation.
 - Resource linked below.
